

6 Applications of Nullstellensatz. Maximal ideals in polynomial rings. Radical ideals.

6.1 Decomposition of affine algebraic sets into affine algebraic varieties.

Proposition 6.1. *Let k be algebraically closed, let $\mathfrak{a} \triangleleft k[x_1, \dots, x_n]$, and let*

$$\mathfrak{a} = \mathfrak{q}_1 \cdot \dots \cdot \mathfrak{q}_m = \mathfrak{q}_1 \cap \dots \cap \mathfrak{q}_m.$$

be the primary decomposition of \mathfrak{a} with the prime ideals $\mathfrak{p}_i = \text{rad}(\mathfrak{q}_i)$. Then $\mathcal{Z}(\mathfrak{q}_i)$ are affine algebraic varieties.

Proof. Clearly

$$\mathcal{Z}(\mathfrak{a}) = \mathcal{Z}(\mathfrak{q}_1 \cap \dots \cap \mathfrak{q}_m) = \mathcal{Z}(\mathfrak{q}_1) \cup \dots \cup \mathcal{Z}(\mathfrak{q}_m),$$

and $\mathcal{Z}(\mathfrak{q}_i)$ is a variety, since $\mathcal{I}(\mathcal{Z}(\mathfrak{q}_i)) = \text{rad}(\mathfrak{q}_i) = \mathfrak{p}_i$ is prime, $i \in I$. □

6.2 Maximal ideals in polynomial rings.

Lemma 6.2. *Let A be a commutative ring, let $f \in A[x_1, \dots, x_n]$. If $f(a_1, \dots, a_n) = 0$ for some $(a_1, \dots, a_n) \in A^n$, then there exist polynomials $g_1, \dots, g_n \in A[x_1, \dots, x_n]$ such that*

$$f = (x_1 - a_1)g_1 + \dots + (x_n - a_n)g_n.$$

Proof. If $n = 1$, consider the identity:

$$x^m - a^m = (x - a)(x^{m-1} + ax^{m-2} + \dots + a^{m-2}x + a^{m-1}).$$

Say $f(x_1) = b_0 + b_1x_1 + \dots + b_lx_1^l$. Since $f(a_1) = 0$, we get

$$\begin{aligned} f(x_1) &= f(x_1) - f(a_1) \\ &= (b_0 + b_1x_1 + \dots + b_lx_1^l) - (b_0 + b_1a_1 + \dots + b_la_1^l) \\ &= b_1(x_1 - a_1) + b_2(x_1^2 - a_1^2) + \dots + b_l(x_1^l - a_1^l), \end{aligned}$$

so that $f(x_1) = (x_1 - a_1)g(x_1)$ for a suitably defined $g \in A[x_1]$.

If $n > 1$ and the Lemma is true for polynomials in $n - 1$ variables, then consider the polynomial

$$g(x_1, \dots, x_{n-1}) = f(x_1, \dots, x_{n-1}, a_n) \in k[x_1, \dots, x_{n-1}].$$

By the inductive hypothesis:

$$g(x_1, \dots, x_{n-1}) = (x_1 - a_1)g_1 + \dots + (x_{n-1} - a_{n-1})g_{n-1},$$

for some $g_1, \dots, g_{n-1} \in k[x_1, \dots, x_{n-1}]$. Moreover

$$\begin{aligned} f(x_1, \dots, x_n) &= \underbrace{f(x_1, \dots, x_n) - f(x_1, \dots, x_{n-1}, a_n)}_{\in A[x_1, \dots, x_{n-1}][x_n]} + \underbrace{f(x_1, \dots, x_{n-1}, a_n)}_{\in A[x_1, \dots, x_{n-1}]} \\ &= (x_n - a_n)g_n(x_1, \dots, x_n) + (x_1 - a_1)g_1 + \dots + (x_{n-1} - a_{n-1})g_{n-1} \end{aligned}$$

by the result for $n = 1$ and the inductive step. \square

Proposition 6.3. *Let k be algebraically closed and let $\mathfrak{m} \triangleleft k[x_1, \dots, x_n]$. Then \mathfrak{m} is maximal if and only if $\mathfrak{m} = (x_1 - a_1, \dots, x_n - a_n)$, for some $a_1, \dots, a_n \in k$.*

Proof. The ideal $(x_1 - a_1, \dots, x_n - a_n)$ is maximal as the kernel of the homomorphic map $k[x_1, \dots, x_n] \rightarrow k$ given by $f \mapsto f(a_1, \dots, a_n)$.

Conversely, let \mathfrak{m} be a maximal ideal. By Lemma 5.15 the set $\mathcal{Z}(\mathfrak{m})$ is nonempty, hence it contains an element $(a_1, \dots, a_n) \in k^n$. Consider the ideal $\mathfrak{a} = (x_1 - a_1, \dots, x_n - a_n)$. As before, \mathfrak{a} is maximal. Since

$$\mathcal{Z}(\mathfrak{a}) = \{(a_1, \dots, a_n)\} \subseteq \mathcal{Z}(\mathfrak{m})$$

we get that

$$\mathcal{I}(\mathcal{Z}(\mathfrak{a})) \supseteq \mathcal{I}(\mathcal{Z}(\mathfrak{m})).$$

$\mathcal{I}(\mathcal{Z}(\mathfrak{a}))$ is a proper ideal, for otherwise $(a_1, \dots, a_n) \in \mathcal{Z}(\mathfrak{a}) = \mathcal{Z}(\mathcal{I}(\mathcal{Z}(\mathfrak{m}))) = \mathcal{Z}(1) = \emptyset$, which is a contradiction. A \mathfrak{m} is maximal:

$$\mathcal{I}(\mathcal{Z}(\mathfrak{a})) = \mathcal{I}(\mathcal{Z}(\mathfrak{m})) = \mathfrak{m}.$$

On the other hand $\mathcal{I}(\mathcal{Z}(\mathfrak{a})) \supseteq \mathfrak{a}$, and hence $\mathfrak{a} \subseteq \mathfrak{m}$. But as \mathfrak{m} is maximal, this yields $\mathfrak{a} = \mathfrak{m}$. \square

Corollary 6.4. *Let k be algebraically closed.*

1. *If $\mathfrak{m} \triangleleft k[x_1, \dots, x_n]$ is a maximal ideal, then $\mathcal{Z}(\mathfrak{m})$ is a singleton.*
2. *For every $\underline{a} \in k^n$ the ideal $\mathcal{I}(\underline{a})$ is maximal.*

Proof. The first part follows directly from Proposition 6.3. For the second one take $(a_1, \dots, a_n) \in k^n$ and consider the maximal ideal $\mathfrak{m} = (x_1 - a_1, \dots, x_n - a_n) \triangleleft k[x_1, \dots, x_n]$. If $f \in \mathfrak{m}$, then $f \in \mathcal{I}(\{(a_1, \dots, a_n)\})$, so that $\mathfrak{m} \subseteq \mathcal{I}(\{(a_1, \dots, a_n)\})$. But then $\mathfrak{m} = \mathcal{I}(\{(a_1, \dots, a_n)\})$. \square

Proposition 6.5. *Let k be algebraically closed. The map*

$$\mathcal{I}: \text{Var } k^n \rightarrow \text{Spec } k[x_1, \dots, x_n], \quad V \mapsto \mathcal{I}(V)$$

is a bijection. In particular singleton sets are mapped onto maximal ideals, and the inverse map is given by

$$\mathcal{Z}: \text{Spec } k[x_1, \dots, x_n] \rightarrow \text{Var } k^n, \quad \mathfrak{p} \mapsto \mathcal{Z}(\mathfrak{p}).$$

Proof. For an affine algebraic variety $V \subseteq k^n$, $\mathcal{Z}(\mathcal{I}(V)) = V$, by Remark 4.6.3 and, for a prime ideal $\mathfrak{p} \triangleleft k[x_1, \dots, x_n]$, $\mathcal{I}(\mathcal{Z}(\mathfrak{p})) = \text{rad } \mathfrak{p} = \mathfrak{p}$, by Hilbert Nullstellensatz. Moreover, singletons are mapped onto maximal ideals, by Corollary 6.4. \square

6.3 Radical ideals.

Definition 6.6. *An ideal \mathfrak{a} of a ring A is called **radical**, if $\mathfrak{a} = \text{rad}(\mathfrak{a})$.*

Lemma 6.7. *Let A be a ring. An ideal $\mathfrak{a} \triangleleft A$ is radical if and only if the ring A/\mathfrak{a} does not have nonzero nilpotents.*

Proof. Let $\kappa: A \rightarrow A/\mathfrak{a}$ be the canonical epimorphism. We claim that

$$\text{rad } \mathfrak{a} = \kappa^{-1}(\text{Nil}(A/\mathfrak{a})).$$

Indeed, for $x \in A$:

$$\begin{aligned} x \in \text{rad } \mathfrak{a} &\Leftrightarrow x^n \in \mathfrak{a} \text{ for some } n \in \mathbb{N} \\ &\Leftrightarrow x + \mathfrak{a} \in \text{Nil}(A/\mathfrak{a}) \\ &\Leftrightarrow x \in \kappa^{-1}(\text{Nil}(A/\mathfrak{a})). \end{aligned}$$

Therefore

$$\mathfrak{a} = \text{rad } \mathfrak{a} \Leftrightarrow \mathfrak{a} = \kappa^{-1}(\text{Nil}(A/\mathfrak{a})) \Leftrightarrow \text{Nil}(A/\mathfrak{a}) = \mathfrak{a},$$

which means that \mathfrak{a} is radical if and only if the only element nilpotent in A/\mathfrak{a} is the zero element. \square

Proposition 6.8. *Let k be algebraically closed and let $\mathfrak{a} \triangleleft k[x_1, \dots, x_n]$. Then \mathfrak{a} is radical if and only if $\mathfrak{a} = \mathcal{I}(V)$ for some affine algebraic set $V \subset k^n$.*

Proof. If \mathfrak{a} is radical, that is $\mathfrak{a} = \text{rad } \mathfrak{a}$, then by Hilbert Nullstellensatz $\mathcal{I}(\mathcal{Z}(\mathfrak{a})) = \text{rad } \mathfrak{a} = \mathfrak{a}$, that is $\mathfrak{a} = \mathcal{I}(V)$, where $V = \mathcal{Z}(\mathfrak{a})$.

Conversely, if $\mathfrak{a} = \mathcal{I}(V)$, then $\mathcal{Z}(\mathfrak{a}) = \mathcal{Z}(\mathcal{I}(V)) = V$, so that by Hilbert Nullstellensatz

$$\text{rad } \mathfrak{a} = \mathcal{I}(\mathcal{Z}(\mathfrak{a})) = \mathcal{I}(V) = \mathfrak{a}. \quad \square$$

Proposition 6.9. *Let k be algebraically closed and let $\mathfrak{a} \triangleleft k[x_1, \dots, x_n]$ be a radical ideal. Then \mathfrak{a} has a unique decomposition into prime ideals $\mathfrak{p}_1, \dots, \mathfrak{p}_r \triangleleft k[x_1, \dots, x_n]$:*

$$\mathfrak{a} = \mathfrak{p}_1 \cap \dots \cap \mathfrak{p}_r \quad \text{with } \mathfrak{p}_i \not\subseteq \mathfrak{p}_j, \text{ for } i \neq j.$$

Proof. Let

$$\mathcal{Z}(\mathfrak{a}) = V_1 \cup \dots \cup V_r$$

be the decomposition of the affine algebraic set $\mathcal{Z}(\mathfrak{a})$ into a union of pairwise incomparable affine algebraic varieties. Clearly

$$\mathcal{I}(\mathcal{Z}(\mathfrak{a})) = \mathcal{I}(V_1) \cap \dots \cap \mathcal{I}(V_r),$$

and every ideal $\mathcal{I}(V_i)$ is prime. From the incomparability of V_i 's it follows that $\mathcal{I}(V_i)$'s are also incomparable. By Hilbert Nullstellensatz $\text{rad } \mathfrak{a} = \mathcal{I}(\mathcal{Z}(\mathfrak{a}))$, so that – as \mathfrak{a} is radical – we get that

$$\mathfrak{a} = \mathcal{I}(V_1) \cap \dots \cap \mathcal{I}(V_r).$$

is a decomposition of \mathfrak{a} into pairwise incomparable prime ideals of $k[x_1, \dots, x_n]$.

In order to show that such a decomposition is unique, suppose that

$$\mathfrak{a} = \mathfrak{p}_1 \cap \dots \cap \mathfrak{p}_r = \mathfrak{q}_1 \cap \dots \cap \mathfrak{q}_s$$

are two decompositions into pairwise incomparable prime ideals. But then

$$\mathcal{Z}(\mathfrak{a}) = \mathcal{Z}(\mathfrak{p}_1) \cup \dots \cup \mathcal{Z}(\mathfrak{p}_r) = \mathcal{Z}(\mathfrak{q}_1) \cup \dots \cup \mathcal{Z}(\mathfrak{q}_s)$$

are two decompositions of $\mathcal{Z}(\mathfrak{a})$ into affine algebraic varieties with incomparable summands. Consequently, $r = s$ and after a conceivably necessary change of labelling $\mathcal{Z}(\mathfrak{p}_i) = \mathcal{Z}(\mathfrak{q}_i)$, so that $\mathfrak{p}_i = \mathfrak{q}_i$, $i \in \{1, \dots, r\}$. \square
